Abstract

Vasculitis is defined as a vascular inflammation which may be localized or systemic and mostly idiopathic. Usually it affects several organs of the body such as skin, kidneys and lungs. Vasculitis is one of the biggest challenges in medical research diagnostics, in nonspecific clinical presentation, as it develops slowly over few weeks to months. In addition, to confirm this, the diagnostic laboratory tests are required and sometimes biopsy is required to be done of the affected artery or serology. To cure this ailment, it is essential to opt for a therapy for symptomatic improvement, induction, remission and decreased mortality.

Keywords

Rheumatoid Arthritis; Vasculitis; Vasculitis Cutaneous

Introduction

Systemic vasculitis, has for many years been a diagnostic challenge in the field of clinical medicine and rheumatology. Among these, rheumatoid vasculitis, a rare and serious complication of Rheumatoid Arthritis (RA) [1,2]. Rheumatoid vasculitis is a form of cutaneous presentation with an annual incidence of 12.5 patients/1,000,000, typically affecting small and medium vessels, with associated peripheral neuropathy (very often motor), digital gangrene.
nail bed infarctions and palpable purple [3]. The spectrum of clinical injuries reported in rheumatoid vasculitis is wide and varies with the size and location of the affected vessels and the extent of the disease [4]. It is a rare and serious complication that must be diagnosed early, given the great interference in the evolution, treatment and prognosis of the underlying disease. The study was aimed to describe a case of RA evolving with rheumatoid vasculitis, a rare and serious condition.

**Case Report**

A 63 year old woman (non-smoker) with a history of rheumatoid arthritis from the past 15 years, characterized by rheumatoid factor elevated titers, erosive poliarthritits and positive testing for anti-CCP antibodies. The treatment included prednisolone, methotrexate and hydroxicloroquine. Despite of certain treatments, she developed isquemic ulcer in a left hand dorsum and nailfod infarction and digital ischemia of the left fingers (Fig. 1 and 2).

The image clearly shows a typical rheumatoid hand, with ulnar deviation, metacarpophalangeal subluxation, atrophy of interosseous muscles and deformities (swan’s neck and boutonnière). There are two types of rheumatoid vasculitis, demonstrated by ulceration in the area of third metacarpophalangeal joint and periungual infarction in the second one, as well as the discrete points of ischemia in the digital pulps. This image elaborates the heterogeneity of the clinical presentations of this single entity [5].
